 CC 7-8 (Enzymes)  
 AB Despite recent progress, the understanding of enzymes remains limited: the  
 prediction of the changes that should be introduced to alter their  
 properties or catalytic activities in an expected direction remains  
 difficult. An alternative to rational design is selection of mutants  
 endowed with the anticipated properties from a large collection of  
 possible solns. generated by random mutagenesis. The authors describe  
 here a new technique of in vitro selection of genes on the basis of the  
 catalytic activity of the encoded enzymes. The gene coding for the enzyme  
 to be engineered is cloned into the genome of a **filamentous**  
 phage, whereas the enzyme itself is displayed on its surface, creating a  
 phage enzyme. A bifunctional organic label containing a suicide inhibitor of  
 the  
 enzyme and a ligand with high affinity for an immobilized receptor are  
 constructed. On incubation of a mixture of phage enzymes, those phages  
 showing an activity on the inhibitor under the conditions of the experiment are  
 labeled. These phages can be recovered by affinity chromatog. The design  
 of the label and the factors controlling the selectivity of the selection  
 are analyzed. The advantages of the technique and its scope in terms of  
 the enzymes that can be engineered are discussed.
